

FloorGuide: the right answer from the **right binder**.

For floor supervisors. Ask in plain words; get the answer from the safety procedure, the maintenance manual, or the quality standard, with the page it came from, and a work order written up when a machine is due.

● Safety procedures

● Maintenance manuals

● Quality standards

1 The problem

When a machine acts up on Line 3, Dana has three binders that might hold the answer. Today she walks to the office, guesses which binder applies, or asks whoever is nearby.

The quick card on the wall and the manual in the drawer do not always agree, and nothing tells her which one wins. A wrong guess on a safety step is not a paperwork problem.

2 What this does for you

- Picks the right binder for the question and answers from it, showing the document, the passage, and which kind of source it was.
- When two documents disagree, says which one governs and which one is out of date, instead of splitting the difference.
- Works out whether a machine is due for service from its meter readings and the manual's interval, by fixed arithmetic, never a guess. A missing or backwards reading gets a plain refusal that names what is wrong.
- When service is due, writes the work order for you: machine, task, priority, and the manual section behind it.

3 What you do now

- Ask the question the way you would ask a colleague.
- Read the answer and the source it came from.
- If a work order was drafted, read it and press **Approve** or **Reject** .
- Tell it once which line you are on. It remembers next time.

4 What stays in your control

- Nothing is filed, sent, or changed without your Approve. Reject throws the draft away.

- It will never tell you to skip a safety step, and it cannot approve anything itself.
- A document that tries to give it orders is thrown out before it is read, and the screen says so.
- Every answer was graded against an answer key before you saw this page, and the grading fails on purpose if a wrong answer slips through.

BEFORE

Minutes per question. A walk to the office to discuss between two documents that disagree. Service dates tracked by memo.

AFTER

One question. One answer with its source. A button for the work order. The safety procedure always wins.

What it is worth

Illustrative numbers, written so they can be swapped for the plant's own.

~40 min

BACK PER SUPERVISOR, PER SHIFT

About six documentation questions a shift, each down from roughly eight minutes (walk, look up, ask around) to about one.

~2,000 hrs

A YEAR, ACROSS THE PLANT

Six supervisors, two shifts, 250 working days. Time that goes back to the line instead of the office.

1 missed service

IS THE REAL COST

A filter run 30 hours past its interval is how a pump starts to fail. One unplanned press stop costs more than a year of this. A wrong guess on a lockout step costs more than money.

How to make these real: count a week of shift-log questions and minutes per answer; use the plant's own figure for an hour of unplanned downtime.

Prototype. Every document, machine, and person here is invented.

Nothing leaves without your click.
